ACKNOWLEDGMENTS

The *1996 Utah Health Status Survey* was funded by the Utah State Legislature. The Office of Public Health Data, Bureau of Surveillance and Analysis, under the direction of Robert T. Rolfs, MD, provided general oversight for the project. It is the mission of the Office of Public Health Data to facilitate, coordinate, and assure the appropriate collection, analysis, and interpretation of accurate health data for purposes of surveillance, policy development, and program planning and evaluation.

1996 Utah HSS Planning Committee

Chair: Lois M. Haggard, PhD, Bureau of Surveillance and Analysis, UDOH

Staff: Kimberly Bangerter, Bureau of Surveillance and Analysis, UDOH

Members:

Sherrie Ahlstrom, RN, BSN, Tooele County Health Department

Denise Beaudoin, MD, MSPH, Chronic Disease Team, UDOH

John Brockert, MSPH, Bureau of Vital Records and Health Statistics, UDOH

Ken Buchi, MD, Veteran's Administration Hospital

Gary L. Edwards, MS, CHES, Southwest Utah Public Health Department

Rebecca Giles, BS, CHES, Health Promotion Team, UDOH

Rich Kerber, PhD, Utah Cancer Registry, University of Utah

Kirin McInnis, MA, Governor's Office of Planning and Budget

Barry Nangle, PhD, Bureau of Vital Records, UDOH

Fineasi Nau, MA, Governor's Office of Polynesian Affairs

Luis Paita, PhD, Office of Health Data Analysis, UDOH

Lorena Riffo, JD, Governor's Office of Hispanic Affairs

Robert T. Rolfs, MD, Bureau of Surveillance and Analysis, UDOH

Darryl L. Snyder, Bureau of Surveillance and Analysis, UDOH

Kevin Thompson, MS, Weber/Morgan District Health Department

Michael B. Toney, PhD, Population Research Laboratory, Utah State University

Kim Wixon, MBA, General Services, UDOH

Wu Xu, PhD, Division of Community and Family Health Services, UDOH

The report was developed and prepared by:

Kirsten Davis

Kim Bangerter

PREFACE

The information in this report is based on data collected in the 1996 Utah Health Status Survey. The survey represents the third of its type, with previous surveys conducted in 1986 and 1991. It provides information on a variety of topics related to health status and health care delivery systems at statewide and health district levels. These topics are presented in separate reports released in 1997 or due to be released in 1998 under the headings listed below.

Health Insurance Coverage
Health Care Access and Utilization
Health Status in Utah
Socio-Economic Status and Health
Lifestyle Factors: Alcohol, Tobacco, Exercise, and 5-A-Day

Chronic Medical Conditions
Preventive Health Screening
Injuries in Utah
Interpersonal Violence
Hearing, Vision, and Speech Disorders

The survey was funded by a one-time legislative appropriation and was designed, analyzed, and reported by the Utah Department of Health, Bureau of Surveillance and Analysis. The survey sample was designed to be representative of Utahns, and is perhaps best described as a weighted probability sample consisting of approximately 6,300 households disproportionately stratified by twelve local health districts that cover the entire state.

The Gallup Organization conducted the telephone interviews using computer-assisted random digit dialing techniques. In each household, one adult (age 18 or older) was randomly selected to respond to survey questions about themselves, about the household as a unit, or with regard to each household member. In addition to “core” survey questions that were asked of every household, sets of supplemental questions were administered to different subsets of the overall sample. The survey results were weighted to reflect the age, sex, geographic distribution, and Hispanic status of the population. Selected analyses were adjusted for non-telephone households. The interview process took place over a three month period from June to August, 1996. The cooperation rate was 66.3%. A detailed description of the methodology can be found in the *Technical Notes* section of this report.

The information in this report can be used to facilitate policy and planning decisions. While it is intended for public health program managers, administrators, and other health care professionals in the public and private health care sectors, the report may also be of interest to anyone wishing to inform themselves on the current health situation in Utah.

INTRODUCTION

Socio-economic status (SES) has been recognized as an important determinant of health since the early part of this century. The 1994 conference on “Measuring Social Inequalities in Health” recommended that health data, including government surveys, vital records systems and cancer registries collect and present data on SES. Two of their recommendations were: data collection should include variables that portray occupation, assets, and household composition; and that the data on the relationship between SES and health be available at the state and local level to improve public health program planning.

The adverse effects of severe poverty on health seem undeniable. People with insufficient resources often live in substandard housing, experience poor diets and malnutrition, and have inadequate medical care, all of which contribute to poor health. Gradients in health exist not only between the extremes of SES; people at one income level often possess better health than persons with only slightly less income (Adler, et al., 1994).

Measures of SES traditionally include, income, assets, education, and occupation, or some combination of them. The 1996 Health Status Survey addressed these factors as well as other measures important for exploring the relationship between SES and health status. This survey contained questions about income, education, and assets such as having household savings, health insurance and home ownership. The 1996 survey also examined how respondents rated their jobs. Adults, employed outside the home or who reported their occupation as “keeping house,” were asked how their jobs compare with an “average job.” The present survey also contained several questions regarding such assets as having household savings, having health insurance, and owning their residence.

Research literature implies that health is affected not only by one’s standard of living and working conditions, but also by involvements with family and others in different social contexts (Krieger, Williams, & Moss, 1997). This survey included information about the relationships among individuals in each household. In addition to information on SES, we also asked respondents their religious affiliation and whether they attended services “about once a week or more, or less often than once a week.”

Health status at the community level is often assessed using death rates, incidence or prevalence of disease or disability, or utilization of health care. These methods have important limitations at the community level and even more so at the individual level. An alternative is to use individuals self-reported health status. The Medical Outcomes Study SF-12 (Ware, Kosinski, & Keller, 1996) was developed to provide standard measures of individuals self-reported health status. For this analysis, three items from the SF-12 were selected as indicators of health status. Two SF-12 items asked whether the respondent had “accomplished less” as a result of their physical or mental health. These health indicators were asked of the survey’s 6,131 randomly-selected adult respondents. The third indicator asked whether the individual judged their health status to be “poor,” “fair,” “good,” “very good,” or “excellent.” For these analyses, persons who responded that their health status was “fair” or “poor” were grouped together. This question was asked of all persons in the survey. SES can be unstable and its measurement inaccurate for young adults, so this analysis was restricted to adults age 25 years or over.

Socio-Economic Status and Health is organized into three sections: Highlights; Reference Tables and a Technical Appendix.

The **Highlights** section presents figures that illustrate the relationship between the three selected measures of health status and the different measures of SES included in the survey. Several tables are presented together for each measure of SES. In each grouping of figures a figure showing all three indicators of health status is followed by figures showing selected measures of health status stratified by age and/or by sex when different in pattern or magnitude from overall percentages. A final grouping of figures compares measures of health status obtained in the 1986, 1991 and 1996 surveys.

The **Reference Tables** section provides detailed survey estimates and the 95% confidence intervals that correspond with the figures in the Highlights section as well as additional more detailed tabulations. Analyses by local health district are presented for select SES and health status measure.

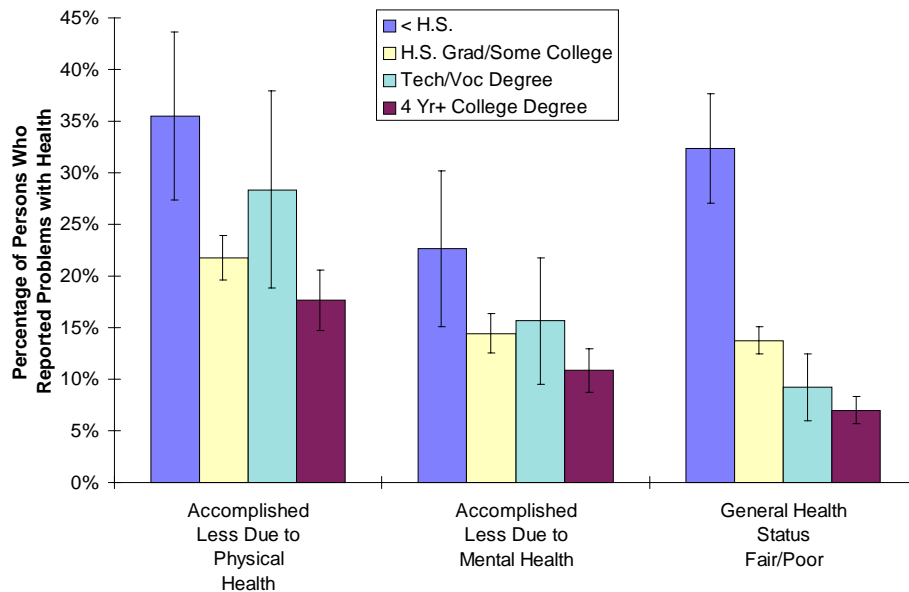

The final section, a **Technical Appendix**, describes the Health Status Survey data collection methodology and analysis process.

SUMMARY OF FINDINGS

- In general, as level of education increased, the percentage of persons reporting problems with health decreased.
 - Women with more formal education were less likely to report problems with physical health.
 - Men with technical/vocational degrees reported problems with physical health more often than did men in any other education category, including those who were not high school graduates.
- As their income level increased, people were progressively less likely to report health problems.
 - The largest differences in reported health status between income levels were for people in their prime wage earning years (age 35-64).
- In general, full time employed people who rated their jobs more favorably, reported better health.
 - About 84% of full time employed Utahns rated their job as “above average” to “excellent”.
 - Those who rated their jobs as “average or below” reported more health problems than those who reported having “excellent” jobs.
- People without health insurance were more likely to report health problems.
 - Uninsured persons age 25-64, were more likely to report problems with mental health than were people with health insurance. That relationship was more pronounced for men.
 - People without health insurance reported more mental health problems than did insured persons.
 - Among people age 35-49, those with health insurance reported much better health status than those without insurance.
- People who had been able to save at least two months annual household income reported better health than people without that amount of savings.
 - Research shows that older people report better mental health than younger people. In this survey, the opposite was true for people who did not have at least two months income saved.
 - People who did not have at least two months income saved were more likely to report fair/poor health. That relationship was more pronounced for females.
- People who owned their home reported better health than those who rented.
- The relationship between religious affiliation and involvement and reported health status was inconsistent.
- Among persons age 25-55, those who were unmarried with children in the household were more likely to report problems with physical and mental health than those in other family household structures.
- People with the lowest socio-economic status reported more health problems in all three survey years, 1986, 1991, 1996.
 - For those living in poverty, the percentage reporting fair/poor health increased between 1986 and 1996, whereas no such increase was found among those living above the poverty line.

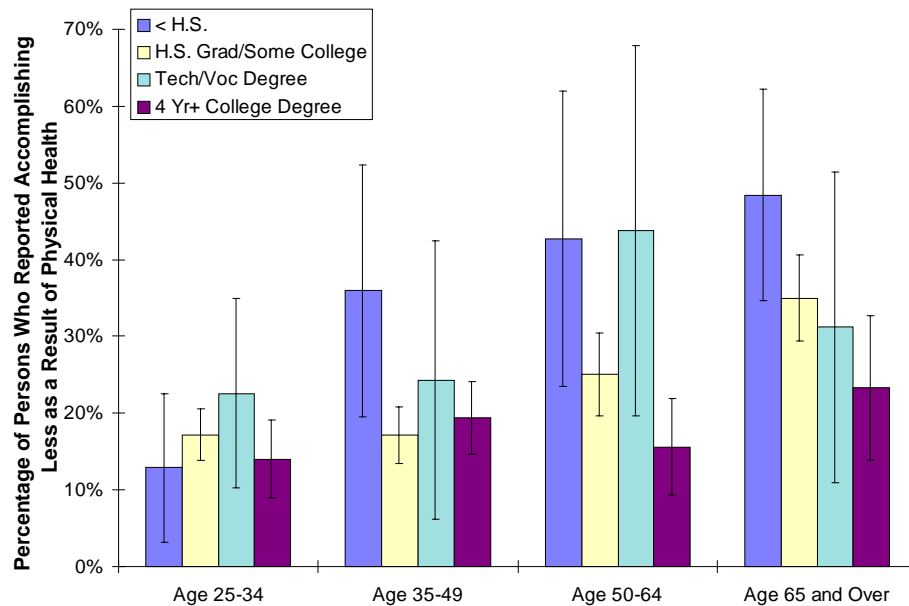

HIGHLIGHTS

Selected Health Status Indicators by Education Level. Utahns Age 25 and Over, 1996.

- In general, as level of education increased, fewer people reported problems with health.
- People with technical/vocational degrees reported more problems with physical health than did those without a high school degree. This could be due to greater physical demands at work for people holding this type of degree.

Accomplished Less Due to Problems with Physical Health by Education Level and Age. Utahns Age 25 and Over, 1996.

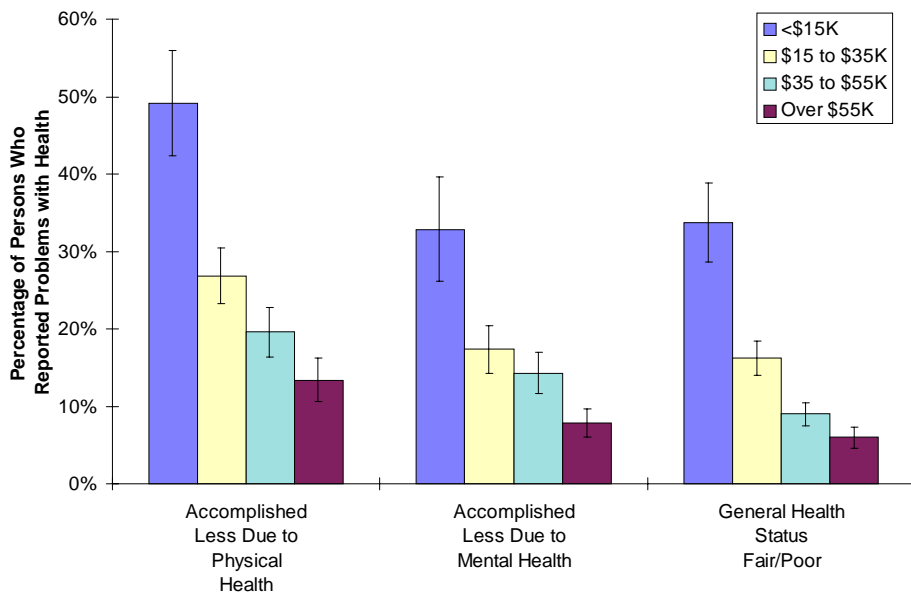

- Among people age 65 and over, we see the expected trend of better physical health as education level increases.
- The relationship between physical health and education level was different for the other age groups.

Accomplished Less Due to Problems with Physical Health by Education Level and Sex. Utahns Age 25 and Over, 1996.

- The percentage of women who reported problems with physical health decreased as education level increased.
- Men with technical/vocational degrees reported worse physical health than men in any other education group.

Selected Health Status Indicators by Annual Household Income. Utahns Age 25 and Over, 1996.

- People with less income reported poorer mental, physical, and general health status.

Fair/Poor Health Status by Annual Household Income and Age. Utahns Age 25 and Over, 1996.

- **Poorer people reported poorer health status at all ages.**
- **The largest differences in health status between income levels were reported by people age 35-64 in their prime income earning years.**

Selected Health Status Indicators by Job Rating. Utahns Age 25 and Over, Full Time Employed, 1996.

- **In general, people who rated their jobs more favorably reported better health status.**
- **About 84% of full time employed persons rated their job above average or excellent, when compared to an “average job.”**

Accomplished Less Due to Problems with Physical Health by Job Rating and Sex.
Utahns Age 25 and Over, Full Time Employed, 1996.

- **The relationship between job ratings and physical health was stronger for women than for men.**

Accomplished Less Due to Problems with Physical Health by Job Rating and Age.
Utahns Age 25 and Over, Full Time Employed, 1996.

- **In general, both older and younger people who rated their job as average or below also reported poorer physical health.**

Selected Health Status Indicators by Health Insurance Coverage. Utahns Age 25-64, 1996.

- **People without health insurance reported poorer health on all three measures.**

Accomplished Less Due to Problems with Physical Health by Health Insurance Coverage. Utahns Age 25-64, 1996.

- **The difference in health status between insured and uninsured persons was largest for people age 35-49.**
- **Uninsured people were not significantly more likely to report physical health problems in the other age groups.**

Accomplished Less Due to Problems with Mental Health by Health Insurance Coverage and Sex. Utahns Age 25-64, 1996.

- **Uninsured men and women were significantly more likely to report problems with mental health than were people with health insurance coverage. That relationship was more pronounced for men.**

Problems with Mental Health by Health Insurance Coverage and Age. Utahns Age 25-64, 1996.

- **Among persons age 35-49 and 50-64, the uninsured were significantly more likely to report mental health problems than insured persons.**

Selected Health Status Indicators by Household Savings.
Utahns Age 25 and Over, 1996.

- **People with at least two months income saved reported better health than people without that much savings.**

Accomplished Less Due to Problems with Mental Health by Household Savings and Age. Utahns Age 25 and Over, 1996.

- **Research shows that as people age they report better mental health. That trend was evident only for people with two months income saved.**
- **For people without two months income saved, problems with mental health increased with age.**

Fair/Poor Health Status by Household Savings and Sex.
Utahns Age 25 and Over, 1996.

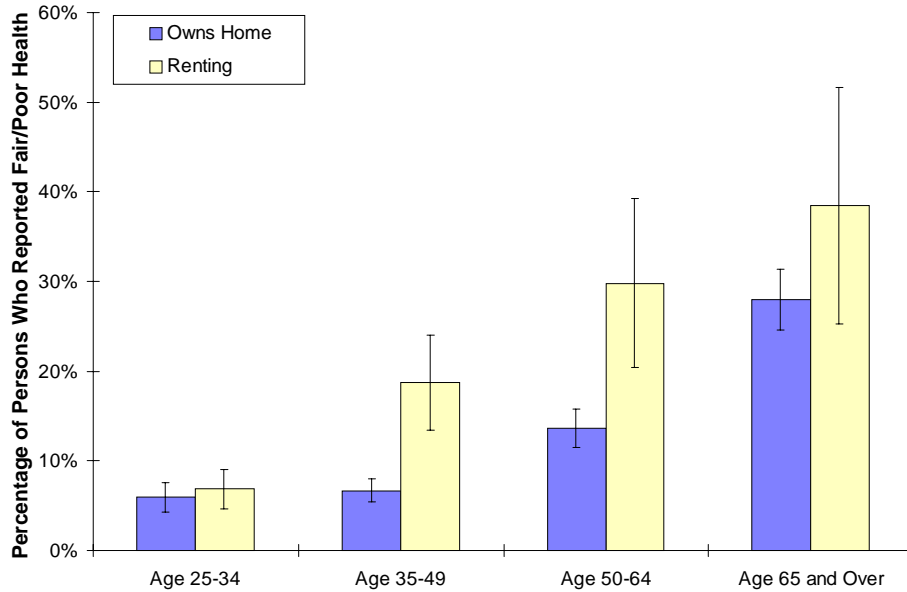

- For both men and women, those who did not have two months income saved were more likely to report fair/poor health. That relationship was more pronounced for women.

Selected Health Status Indicators by Home Ownership.
Utahns Age 25 and Over, 1996.

- People who owned their home reported better health than those who rented.

Fair/Poor Health Status by Home Ownership and Age. Utahns Age 25 and Over, 1996.

- People who rent were more likely to report fair/poor health than those who own their home at ages over 35 years.
- Among young adults, renting a residence may not indicate lower socioeconomic status.

Fair/Poor Health Status by Education Level and Year. Utahns Age 25 and Over, 1986, 1991, and 1996.

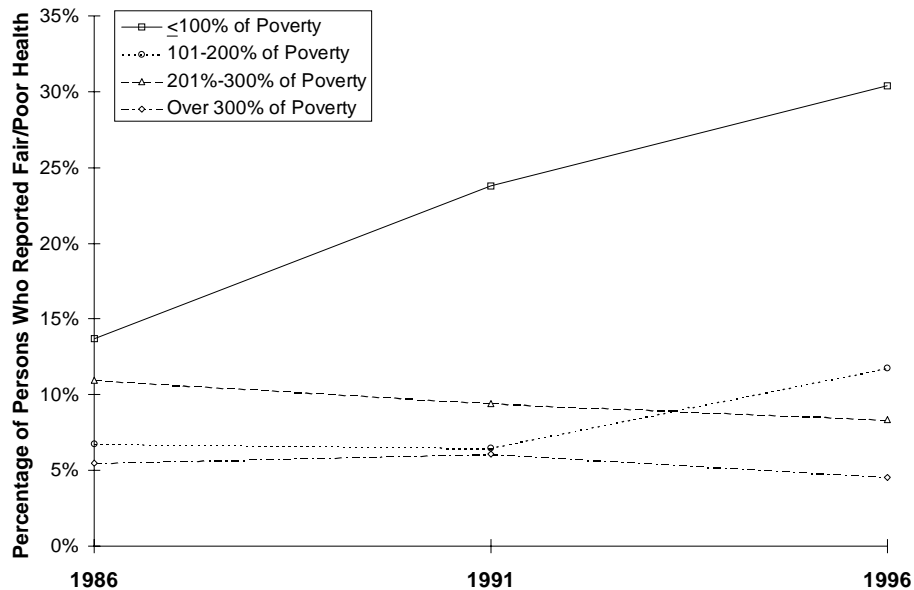

- In general, persons with lower education levels were more likely to report fair/poor health at all three points in time.

Fair/Poor Health Status by Household Poverty Status and Year.
Utahns Age 25 and Over, 1986, 1991, and 1996.

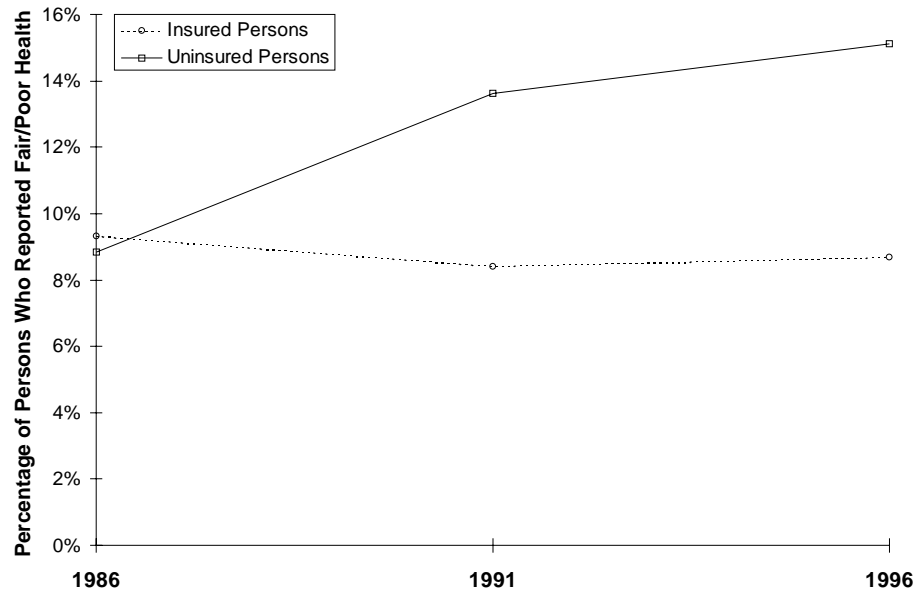

- As people's income increased above the poverty line, they were less likely to report fair/poor health.

Fair/Poor Health Status by Household Poverty Status and Year.
Utahns Age 35-49, 1986, 1991, and 1996.

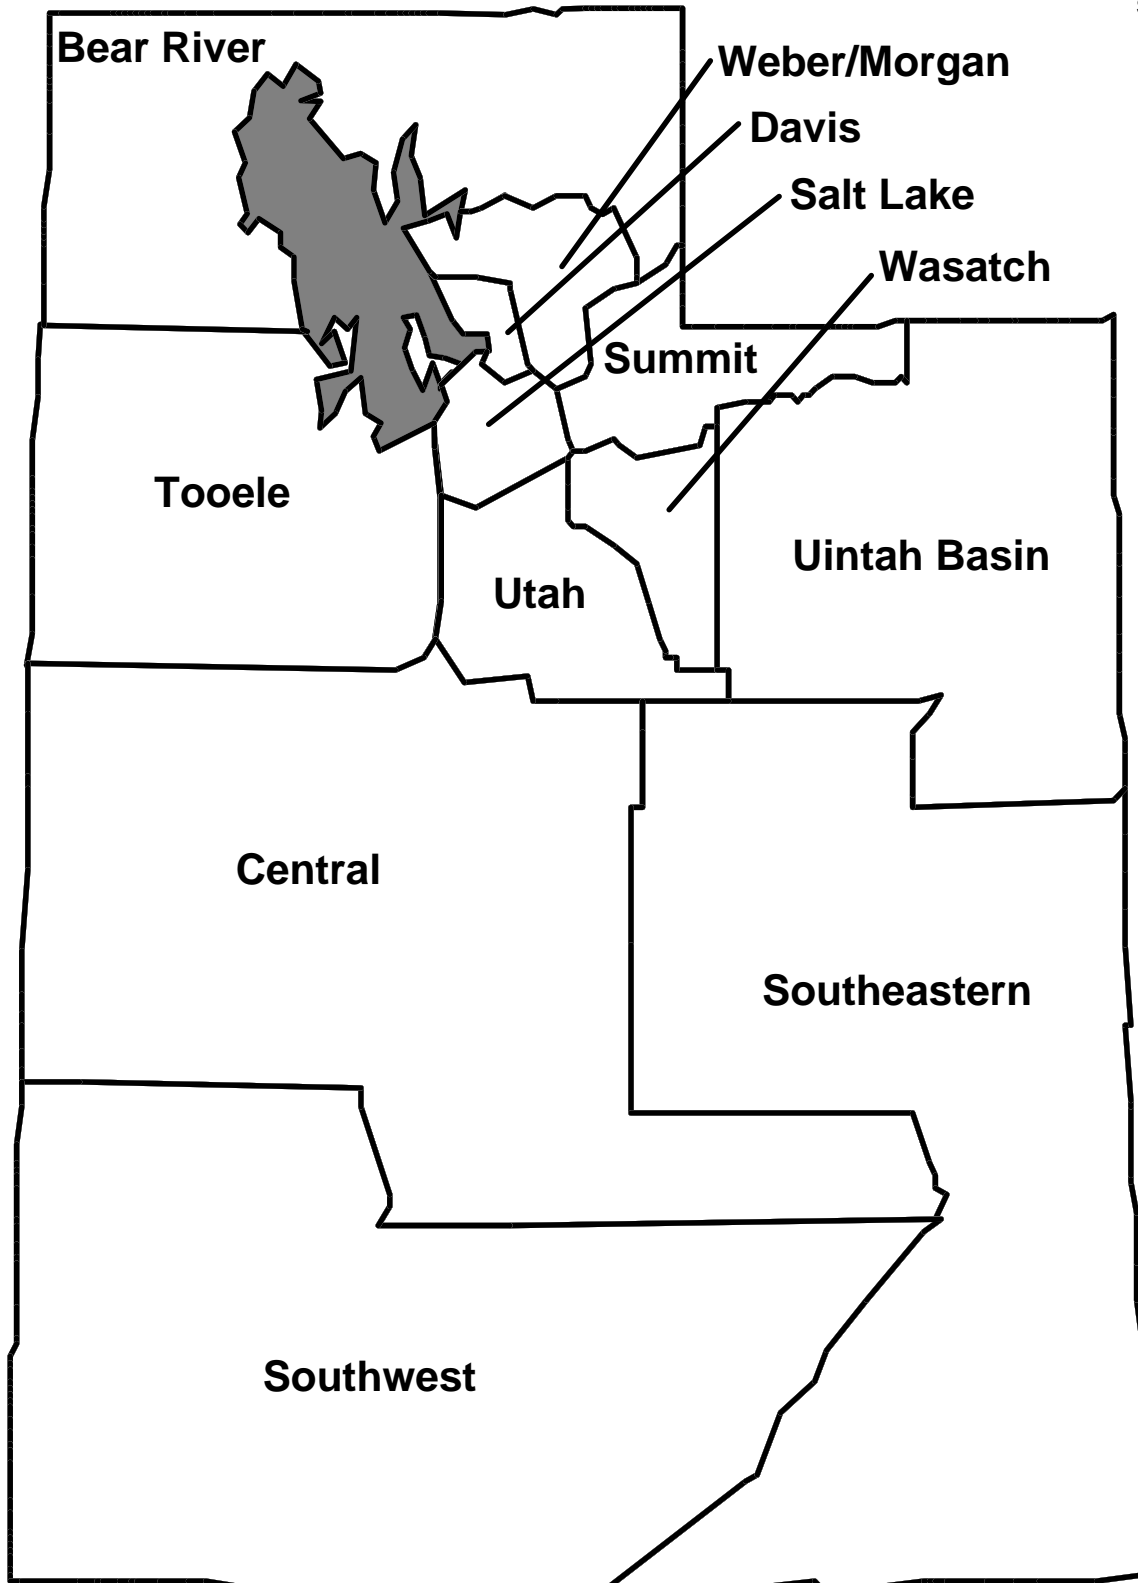

- Health status of persons in their prime income-earning years (age 35-49) who were at or below the poverty line appears to have worsened over time.

Fair/Poor Health Status by Health Insurance Coverage and Year. Utahns Age 25-64, 1986, 1991, and 1996.

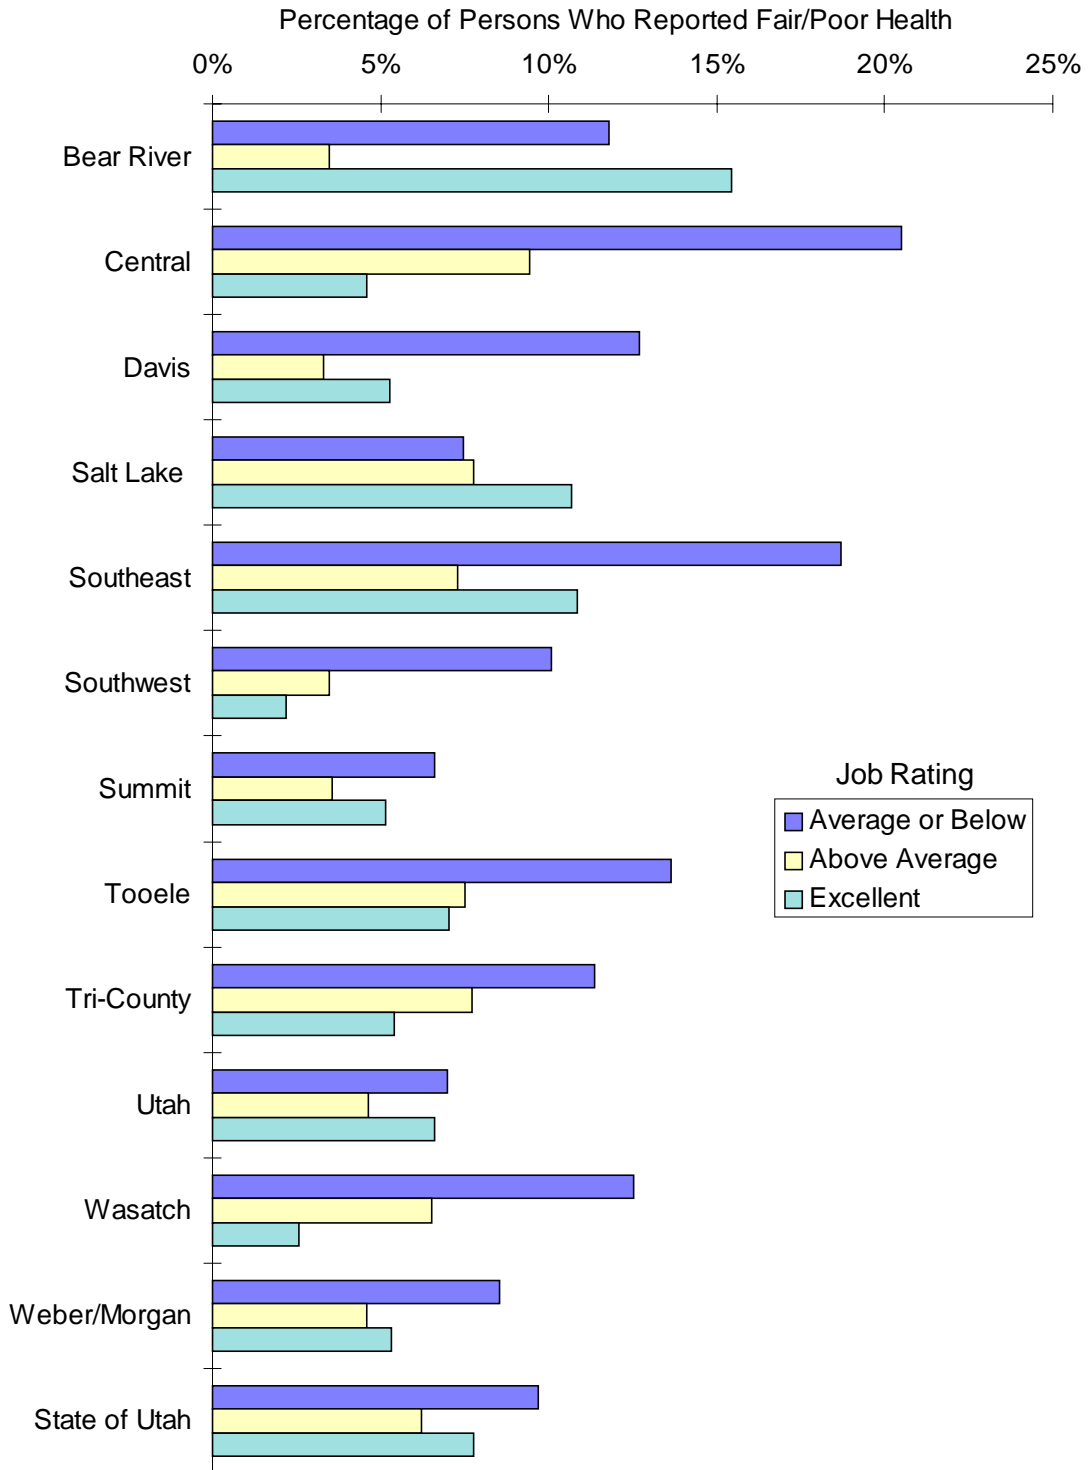

- **The health status of uninsured persons appears to have worsened over time.**

State of Utah
Local Health Departments

Fair/Poor Health Status by Job Rating and Local Health District.
Utahns Age 25 and Over, Full Time Employed, 1996.

- In general, full time employed persons who rated their jobs as only “average” or below were more likely to report fair/poor health status.
- In some health districts, the relationship between job rating and health status differed from that observed for the entire state.

Sample Design

The 1996 Utah Health Status Survey represents the third such survey; previous surveys were conducted in 1986 and 1991. The statistical estimates in this report are based on *1996 Utah Health Status Survey* data.

The sample was a **complex survey sample** designed to be representative of all Utahns. It is best described as a weighted probability sample of approximately 6,300 households disproportionately stratified by twelve local health districts that cover the entire state. Five hundred household interviews were conducted in each health district, except Salt Lake City/County Health District, in which eight hundred household interviews were conducted in order to increase the precision of statewide estimates.

A **single stage, non-clustered, equal probability of selection telephone calling design** was used to generate telephone numbers, more specifically referred to as the *Casady-Lepkowski* (1993) calling design. This method begins by building a *base sampling frame* consisting of all possible telephone numbers from all working prefixes in Utah. Telephone numbers are arranged sequentially into groups of 100 by selecting all telephone numbers within an area code and prefix, plus the first and second digits of the suffix (e.g., 801-538-10XX represents a group that includes all 100 phone numbers between 801-538-1000 and 801-538-1099). Each group of 100 telephone numbers is classified as either high density (at least one residential listing) or low density (no listed residential phone numbers in the group). All low density groups are removed, and high density groups are retained. Telephone numbers are randomly selected from the high-density list. This sampling design ensures that both listed and unlisted phone numbers are included in the sample.

The survey interview was conducted with **one randomly-selected adult** (age 18 or older) in each household. To select this person, Gallup interviewers collected household membership information from the household contact person (the person who answered the telephone). One household member was then selected at random from the list of all household members age 18 or over. Survey questions were then asked about either, 1) all household members, 2) the survey respondent only, 3) a randomly selected adult or child household member (selected using the same method as was used to select the respondent), or 4) the household as a whole. Thus, the survey sample varies, depending on the within-household reference sample that was used for each set of survey questions. Each within-household reference sample has known probabilities of selection and can be generalized to the Utah population.

Survey Data Collection

The Utah Department of Health contracted with The Gallup Organization to collect the survey data. Gallup incorporated the telephone survey instrument into a **computer-assisted random digit dialing software program**, called SURVENT. Interviews were conducted by trained interviewers in a supervised environment across six sites. Interviews were conducted in Spanish when appropriate.

Computer-assisted telephone interviewing was chosen as the method of data collection for several reasons. First, it yields higher response rates, thus resulting in a more representative sample and reducing the amount of bias inherent in mail survey response rates. Second, it helps reduce non-sampling error by standardizing the data collection process. Data-entry errors are reduced because interviewers are not allowed to enter non-valid codes. It was also efficient because it allowed interviewers to enter responses directly into the database.

The survey questionnaire was divided into *core* and *supplemental modules*. Core questions were asked of all households in the sample. Table 1 describes the types of “core” questions that were asked, and about whom they were asked. Notice that *not all questions were asked with regard to everyone in the household*.

Table 1.
CORE MODULE QUESTIONS

<u>Question Topic</u>	<u>Within-Household Reference Sample</u>
Demographic characteristics	All household members
Presence of chronic medical condition	All household members
Health insurance status	All household members
Injury incidence/safety issues	All household members
Lifestyle (smoking, drinking, exercise)	All household members
Subjective mental/physical health (SF12)	Respondent only (randomly-selected adult)
Health screening exam usage	Respondent only (randomly-selected adult)
Access to care/primary provider	Randomly-selected household member of any age
Household-level demographic characteristics	The household as a whole

In addition to the core survey questions (above), one of six different *supplemental modules* was administered to primarily non-overlapping randomly-assigned subsets of (approximately 1,000) households. Table 2 shows the types of questions asked in the supplemental module questions, and about whom they were asked.

Table 2.
SUPPLEMENTAL MODULE QUESTIONS

<u>Type of Question</u>	<u>Within-Household Reference Sample</u>
Limitations of activities	All household members
Migration	Respondent only (randomly-selected adult)
Health Plan Consumer Satisfaction	Respondent only (randomly-selected adult)
Fertility	Respondent or spouse only
Health Care Utilization	Randomly-selected household member of any age
Interpersonal violence	The household as a whole

*Note: All supplemental module questions were asked only of a subset of households.

While both core and supplemental modules yielded sufficient sample sizes to construct state-level estimates for the Utah population, the information collected from supplemental modules was not intended for use in district-level analyses.

Cooperation rate

The interview process took place over a three month period (from June to August, 1996), and resulted in a cooperation rate of 66.3%. If necessary, up to nine telephone attempts were made to contact a selected household. After a randomly-selected survey respondent was identified, up to nine attempts were made to conduct the interview with that person.

Weighting and Estimation Methods

Post-survey weighting adjustments were made so that the Health Status Survey findings could be more accurately generalized to Utah's population. Two types of post-survey weighting adjustments were made, one that adjusted for random sampling variation, and one that adjusted for disproportionate sampling (such as the over-sampling of smaller local health districts across the state). Although the two types of adjustment are distinct conceptually, they were accomplished in a single step.

The post-survey weighting adjustments weighted the sample to be proportionately consistent with the age, sex, geographic, and Hispanic status distribution of the 1996 Utah population. Utah population estimates by sex, single year of age, and county of residence were provided by the Utah Governor's Office of Planning and Budget (GOPB) (the estimates used were those compiled in 1994). Estimates of Utah's Hispanic population for 1996 were derived by calculating the average annual rate of increase of Hispanic persons for each health district using data from 1990 to 1994 Bureau of the Census reports, and then projecting those increases to 1996 GOPB local health district population counts. Total state estimates for Hispanic persons were calculated by summing across local health districts.

The post-survey weighting variables adjusted for the following factors:

1. The number of **phones** in the household.
2. The total **number of persons in the household** to which the data will be generalized (1 for questions that were asked about every household member, the number of adults in the household for questions that were asked only of the respondent, the number of persons in the household for questions that were asked of a randomly-selected household member).
3. The proportion of **Hispanic persons** in each local health district.
4. The **age and sex** distribution of each local health district.
5. The probabilities of selection for each **local health district**.

Population count estimates. Once a percentage was calculated for a variable of interest (e.g., the percentage uninsured) using appropriately weighted survey data, a population count (N) to which the percentage applied was estimated. In some cases analyses referenced certain age or sex groups, Hispanic persons or combinations of Utah counties. These total population group counts were readily available from the sources described earlier. However, for other groups where population counts were largely unavailable (e.g., analyses that examined the distribution of adult males by marital status), the population counts were estimated. This was achieved by multiplying the appropriate 1996 population total for that group (from 1996 GOPB estimates) by a proportion obtained from a frequency distribution or cross tabulation analysis of survey data. For instance, to calculate a population count for adult males who were married, the population of adult males from GOPB was multiplied by percentage of married adult males in the 1996 Utah Health Status Survey sample. Thus, any population count estimates not derived directly from existing age, sex, Hispanic status or county population estimates were derived from 1996 Health Status Survey data, and must be considered estimates.

Missing Values. Another consideration that affected the presentation of the population estimates in table format was the inclusion or exclusion of missing values (“don’t know” and “refused to answer”). Population percentage estimates were calculated after removing the “don’t know” and “refused to answer” responses from the denominator. This, in effect, assumed that persons who gave these answers were distributed identically on the variable of interest to those who gave a valid answer to that variable. For instance, that among those who did not know whether they were insured, we assumed that 90.47% of them were insured and 9.53% were not insured -- percentages identical to those found among the sample members who answered the question with a valid response.

Removing the missing cases from an analysis is rather simple and straightforward for analyses of a single variable. However, when one variable is cross-tabulated by another variable, all missing cases from both variables must be removed from the analysis. Removing the missing cases in itself is not a problem. However, a problem is encountered when a population estimate for a given variable, such as the percentage of all Utahns that have health insurance, differs slightly from an analysis of “all Utahns” versus an analysis of “all Utahns by age group.” This is because the missing cases on the age variable have been removed from one analysis and not from another. Since the percentage of all Utahns that have health insurance was calculated on slightly different samples, the resulting percentage estimates are slightly different. This problem was resolved by reporting the best population estimate available for any given population subgroup. For instance, in the table of insurance rates for all Utahns by age, the population estimate from an analysis that includes Utahns of all ages, regardless of whether they reported missing values on the age variable has been substituted for the original total row in that table. The only drawback to this strategy is that the population count figures for Utahns with and without health insurance in tables like the “Utahns by Age Group” table do

not sum to the same number derived from the analysis of all Utahns regardless of whether they had missing values on the age variable. As a result, the tables appear as though they do not “add up.”

Limitations and Other Special Considerations

Estimates developed from the sample may differ from the results of a complete census of all households in Utah due to two types of error, sampling and non-sampling error. Each type of error is present in estimates based on a survey sample. Good survey design and data collection techniques serve to minimize both sources of error.

Sampling error refers to random variation that occurs because only a subset of the entire population is sampled and used to estimate the finding in the entire population. It is often mis-termed “margin of error” in popular use. Sampling error is expressed as a *confidence interval*. The 95% confidence interval (calculated as 1.96 times the standard error of a statistic) indicates the range of values within which the statistic would fall 95% of the time if the researcher were to calculate the statistic (e.g., a percentage) from an infinite number of samples of size n drawn from the same base population. It is typically expressed as the “plus or minus” term, as in the following example:

“The percentage of those polled who said they would vote for Bill Clinton was 52%, plus or minus 2%.”

Because local health districts were disproportionately stratified and then weighted to reflect the Utah population, the sample was considered a complex survey sample design. Estimating the sampling error for a complex survey design requires special statistical techniques, derived from the standard error for each estimate. SUDAAN software (Research Triangle Institute) was chosen to estimate the standard errors of the survey estimates because it employs a statistical routine (Taylor-series expansion) that accounts for the complex survey design.

Figures in this report include bars showing this estimated confidence interval around the parameter estimate. In cases where the confidence interval was greater in magnitude than the estimate, the estimate was not given. Estimates were not computed where the sample denominators were less than $n=50$. Readers should note that we have always presented the confidence interval as though it were symmetric, that is, of equal value both above and below (plus and minus) the estimate. It is often the case, however, that a confidence interval will be nonsymmetric. This occurs when the distribution is positively or negatively skewed, such as when a percentage is close to 0% or 100%. However, because the software program we use provides only symmetric confidence intervals, we are unable to provide the asymmetric estimates.

Non-sampling error also exists in survey estimates. Sources of non-sampling error include idiosyncratic interpretation of survey questions by respondents, variations in interviewer technique, household non-response to questions, coding errors, and so forth. No specific efforts were made to quantify the magnitude of non-sampling error.

Comparability with other surveys is an issue with all surveys. Differences in survey design, survey questions, estimation procedures, the socio-demographic and economic context, and changes in the structure and financing of the health care delivery system may all affect comparison between the 1996 Utah Health Status Survey and other surveys, including those conducted by the U.S. Bureau of the Census, the Behavioral Risk Factor Surveillance System surveys, and previous Utah Department of Health, Health Status Surveys.

Telephone surveys exclude certain population segments from the sampling frame, including persons in group living quarters (e.g., military barracks, nursing homes) and households without telephones. At the time of the 1990 Decennial Census, only four percent of Utah households were without telephone service. Typically, telephone surveys are biased because telephone households under-represent lower income and certain minority populations. In addition, studies have shown that non-telephone households tend to have lower rates of health care utilization (especially dental care), poorer health habits and health status, and lower rates of health insurance coverage (Thornberry and Massey, 1988).

Despite these overall disparities between telephone and non-telephone households, new survey research (Keeter, 1995) suggests that a similarity exists between data from non-telephone households and telephone households that experienced an interruption in service over the past 12 months. This similarity exists because many, if not most, households currently without telephones did have service in the recent past, and will have service again in the future. Therefore, certain households with telephones (those that had a recent interruption in service) are representative of “nonphone” households, allowing health status survey estimates that have been corrected for telephone noncoverage bias to be produced where indicated.
